BACKGROUND OF THE INVENTION

The invention relates to electronic image methods and devices, and, more particularly, to digital communication and storage systems with compressed images.

Video communication (television, teleconferencing, Internet, and so forth) typically transmits a stream of video frames (pictures, images) along with audio over a transmission channel for real time viewing and listening or storage. However, transmission channels frequently add corrupting noise and have limited bandwidth. Consequently, digital video transmission with compression enjoys widespread use. In particular, various standards for compression of digital video have emerged and include H.261, MPEG-1, and MPEG-2, with more to follow, including in development H.263 and MPEG-4. There are similar audio compression methods.

Tekalp, Digital Video Processing (Prentice Hall 1995), Clarke, Digital Compression of Still Images and Video (Academic Press 1995), and Schafer et al, Digital Video Coding Standards and Their Role in Video Communications, 83 Proc. IEEE 907 (1995), include summaries of various compression methods, including descriptions of the H.261, MPEG-1, and MPEG-2 standards plus the H.263 recommendations and indications of the desired functionalities of MPEG-4. These references and all other references cited are hereby incorporated by reference.

H.261 compression uses interframe prediction to reduce temporal redundancy and discrete cosine transform (DCT) on a block level together with high spatial frequency cutoff to reduce spatial redundancy. H.261 is recommended for use with transmission rates in multiples of 64 Kbps (kilobits per second) to 2 Mbps (megabits per second).
